Collaboration and Competition

Project's Goal

In this environment, two agents control rackets to bounce a ball over a net. If an agent hits the ball over the net, it receives a reward of +0.1. If an agent lets a ball hit the ground or hits the ball out of bounds, it receives a reward of -0.01. Thus, the goal of each agent is to keep the ball in play.

Environment and Project Information

- The project environment is similar to, but not identical to the Tennis environment on the <u>Unity ML-Agents</u>
- The observation space consists of 8 variables corresponding to the position and velocity of the ball and racket. Each agent receives its own, local observation.
 Two continuous actions are available, corresponding to movement toward (or away from) the net, and jumping.
- The task is episodic, and in order to solve the environment, your agents must get an average score of +0.5 (over 100 consecutive episodes, after taking the maximum over both agents).
- After each episode, we add up the rewards that each agent received (without discounting), to get a score for each agent. This yields 2 (potentially different)

- scores. We then take the maximum of these 2 scores. This yields a single score for each episode.
- The environment is considered solved, when the average (over 100 episodes) of those scores is at least +0.5.

Learning Algorithm, Network Structure and Implementation

In this project, MADDPG algorithm used for learning algorithm.

According to <u>Multi-Agent Actor-Critic for Mixed Cooperative-Competitive Environments paper</u>, the motivation behind this algorithm is;

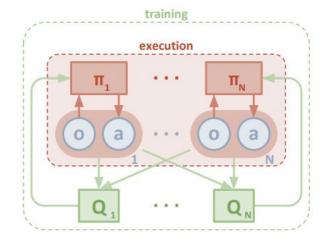

Figure 1: Overview of our multi-agent decentralized actor, centralized critic approach.

• If we know the actions taken by all agents, the environment is stationary even as the policies change

MADDPG Algorithm

Multi-Agent Deep Deterministic Policy Gradient Algorithm

For completeness, we provide the MADDPG algorithm below.

Algorithm 1: Multi-Agent Deep Deterministic Policy Gradient for N agents

```
for episode = 1 to M do
   Initialize a random process N for action exploration
   Receive initial state x
   for t = 1 to max-episode-length do
       for each agent i, select action a_i = \pmb{\mu}_{\theta_i}(o_i) + \mathcal{N}_t w.r.t. the current policy and exploration
       Execute actions a = (a_1, \dots, a_N) and observe reward r and new state \mathbf{x}'
       Store (\mathbf{x}, a, r, \mathbf{x}') in replay buffer \mathcal{D}
       for agent i = 1 to N do
           Sample a random minibatch of S samples (\mathbf{x}^j, a^j, r^j, \mathbf{x}'^j) from \mathcal{D}
           Set y^j = r_i^j + \gamma Q_i^{\boldsymbol{\mu}'}(\mathbf{x}'^j, a'_1, \dots, a'_N)|_{a'_k = \boldsymbol{\mu}'_k(o^j_k)}
           Update critic by minimizing the loss \mathcal{L}(\theta_i) = \frac{1}{S} \sum_j \left( y^j - Q_i^{\mu}(\mathbf{x}^j, a_1^j, \dots, a_N^j) \right)^2
           Update actor using the sampled policy gradient:
                          \nabla_{\theta_i} J \approx \frac{1}{S} \sum_j \nabla_{\theta_i} \boldsymbol{\mu}_i(o_i^j) \nabla_{a_i} Q_i^{\boldsymbol{\mu}}(\mathbf{x}^j, a_1^j, \dots, a_i, \dots, a_N^j) \big|_{a_i = \boldsymbol{\mu}_i(o_i^j)}
       end for
       Update target network parameters for each agent i:
                                                             \theta_i' \leftarrow \tau \theta_i + (1 - \tau)\theta_i'
```

Architecture of Networks:

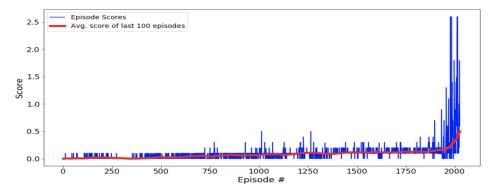

end for end for

- 1. **Architecture of Actor Network**: 2 fully connected hidden layer (256), Relu activation function and batch normalization layer and tanh
- 2. **Architecture of Critic Network:** 2 fully connected hidden layer (256), Activation is Relu and batch normalization

Parameters and Results:

```

Plot of Rewards

Ideas of Future Work:

Proximal Policy Optimization Algorithms

- PPO strikes a balance between ease of implementation, sample complexity, and ease of tuning, trying to compute an update at each step that minimizes the cost function while ensuring the deviation from the previous policy is relatively small.
- Detailed about PPO algorithm can be found in this paper

Here is the algorithm

So that's it! We can finally summarize the PPO algorithm

- 1. First, collect some trajectories based on some policy $\pi_{ heta}$, and initialize theta prime heta'= heta
- 2. Next, compute the gradient of the clipped surrogate function using the trajectories
- 3. Update heta' using gradient ascent $heta' \leftarrow heta' + lpha
 abla_{ heta'} L_{ ext{sur}}^{ ext{clip}}(heta', heta)$
- 4. Then we repeat step 2-3 without generating new trajectories. Typically, step 2-3 are only repeated a few times
- 5. Set $\theta = \theta'$, go back to step 1, repeat.
